

# Progressive Multifocal Leukoencephalopathy (PML)

---

## **WHAT IS PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY?**

Progressive multifocal leukoencephalopathy (PML) is a serious viral infection of the brain.

- Progressive means that this disease gets worse over time.
- Multifocal means that it shows up in several places at the same time.
- Leukoencephalopathy means a disease of the white matter of the brain.

Researchers estimate that about 6% of people with [AIDS](#) develop PML. Most cases of PML show up in people with [CD4 cell counts](#) below 100 cells/mm<sup>3</sup>. The exact rate is hard to know because PML is difficult to diagnose.

Most cases of PML used to be fatal. People diagnosed with PML lived an average of 6 months and most died within 2 years. However, if people with PML start taking strong [antiretroviral medications \(ARVs\)](#) to control their HIV, they can survive much longer. Now more than half of people with HIV and PML survive for at least two years.

The human polyomavirus JC virus (JCV) causes PML. Between 80-85% of all adults are exposed to JCV worldwide. In people with weakened immune systems, JCV can become active.

## **HOW IS PML BE DETECTED?**

The first symptoms of PML are weakness or coordination problems in an arm or leg. There may be difficulty thinking or speaking. Vision and memory problems, seizures, and headaches can occur.

These symptoms can also occur with other [opportunistic infections \(OIs\)](#), including toxoplasmosis, [lymphoma](#), inner ear infections, or [cryptococcal meningitis](#). It is important to rule out these other diseases.

PML can be diagnosed using a scan of the brain by magnetic resonance imaging (MRI). Another way to test for PML is by checking spinal fluid. The sample is taken by inserting a needle into the spinal canal. This procedure is called a spinal tap.

## **HOW IS PML TREATED?**

A major problem with treating any brain infection is the blood-brain barrier. The blood vessels around the

brain are different from the rest of the body. They are tightly woven to protect the brain from toxic substances. Chemicals that dissolve in fat can get through. Those that dissolve in water can't. Unfortunately, this includes most antibiotics and many other medications.

There is currently no proven treatment for PML. Research studies have had conflicting results. Some possible treatments have not been carefully studied. However, PML has slowed down or stopped in some patients taking strong ARVs to fight HIV. [Strengthening the immune system](#) is currently the best way to treat PML. This approach might trigger [immune reconstitution inflammatory syndrome \(IRIS\)](#).

Cytosine arabinoside or cytarabine (Ara-C) has been tried as a treatment for PML. It was given intravenously (IV) or pumped directly into the brain. It seemed to work in one small study but not in later ones. Ara-C is very toxic and damages bone marrow.

High-dose zidovudine (AZT, Retrovir) has been tried against PML because it crosses the blood-brain barrier. Other substances that have been tried with different degrees of success include acyclovir, heparin, peptide-T, beta interferon, dexamethasone, mefloquine, n-acetylcysteine, topotecan, and cidofovir.

Because PML can progress rapidly, it is important to begin treatments quickly.

### ***THE BOTTOM LINE***

PML is a viral infection of the brain caused by the JC virus. It is fatal in about 50% of cases. It can be confused with other medical conditions.

There is no approved treatment for PML, although several treatments may be helpful. Strengthening the immune system using [antiretroviral therapy \(ART\)](#) is currently the best approach. Any treatment must be started as early as possible. Combination ART may slow the progress of PML.
