Abstract
HIV self-testing has the potential to improve test access during and after HIV self-testing. We investigated an orientation to see if and how it provided counselling and was nested within an ongoing observational cohort study participants and study staff using 33 semi-structured. The app provided information and guidance while also the strategy gave participants more control in choosing smartphone access and usability issues for older and in expanding test access in South Africa.

A 49-year-old patient notices a painless rash on his shoulder but does not seek care. Months later, his wife asks him to see a doctor, who diagnoses a seborrheic keratosis. Later, when the patient undergoes a screening colonoscopy, a nurse notices a dark macule on his shoulder and advises him to have it evaluated. One month later, the patient sees a dermatologist, who obtains a biopsy specimen of the lesion. The findings reveal a noncancerous pigmented lesion. Still concerned, the dermatologist requests a second reading of the biopsy specimen, and invasive melanoma is diagnosed. An oncologist initiates treatment with systemic chemotherapy. A physician friend asks the patient why he is not receiving immunotherapy.
